The non-perturbative c_{sw} determined by the Schrödinger functional (SF) method with the RG-improved gauge action in dynamical $N_f = 3$ QCD shows a finite volume effect when the numerical simulations are carried out at a constant lattice size L/a . We remove the unwanted finite volume effect by keeping physical lattice extent L at a constant. The details of the method and the result obtained for non-perturbative c_{sw} with a constant L are reported.

1. Introduction

Last year we reported the existence of a sizable finite volume effect in the non-perturbative c_{sw} determined by the Schrödinger functional (SF) method at a fixed lattice size ($L/a = \text{const}$) when the RG-improved gauge action is adopted in full three-flavor QCD [1]. This effect causes a constant deviation from the true non-perturbative value of c_{sw} , and yields $O(a)$ errors in physical observables.

This year we explain our strategy for removing the unwanted finite volume effect from c_{sw} and report the bare coupling dependence of the non-perturbative c_{sw} for three-flavor dynamical QCD.

2. Method and Simulations

The basic strategy to obtain the non-perturbative c_{sw} with the SF setup is described in [2]. We used Eq. (2.17) of [4] for the SF bound-

ary coupling of the RG-improved gauge action. The polynomial Hybrid Monte Carlo (PHMC) algorithm [3] is employed for the numerical simulation of the three-flavor dynamical QCD.

To remove the finite lattice size effect we fix the physical lattice extent L so that a/L corrections vanish with a . This can be achieved by the following steps.

- (1) Define the reference lattice size L^*/a at a bare coupling value g_0^{2*} . This also defines the reference physical lattice extent L^* .
- (2) For other g_0^2 's, the lattice sizes L^*/a at each g_0^2 are estimated by the beta function.
- (3) Determine c_{sw} and κ_c via the PCAC condition with the SF setup at each g_0^2 on the corresponding lattice size L^*/a .

In actual numerical simulations we employ the universal two-loop beta function to estimate L^*/a . This causes a systematic error in the non-perturbative c_{sw} , which could be large in the strong coupling region. This systematic error,

*Presented by K.-I.I.

however, can be partly avoided by defining L^* at the largest coupling value. We can also examine the magnitude of the error by investigating the L/a dependences because the error only appears through the incorrect value of L^*/a .

With the above consideration we take the following setup in the simulations.

- (i) We define L^* so that $L^*/a = 6$ holds at $\beta = 6/g_0^2 = 1.9$.
- (ii) We employ both $L/a = 8$ and 6 at $\beta = 2.0$, and $L/a = 8$ for other weaker couplings.
- (iii) We correct c_{sw} and κ_c at L/a to those at L^*/a using the one-loop correction calculated with the SF setup in finite lattice volume [4].

Although the perturbative error from setup (iii) appears in strong coupling region, the magnitude can be reduced when $L^*/a \sim L/a$ holds and L/a dependence is small. The small L/a dependence is confirmed at $\beta = 2.0$ as shown later. We will briefly discuss the possible resolution of the systematic error from the use of perturbative beta function in the last section.

We use the following non-perturbative tuning condition for c_{sw} and κ .

$$\begin{aligned} M(g_0^2, L/a, \kappa, c_{\text{sw}}) &= 0, \\ \Delta M(g_0^2, L/a, \kappa, c_{\text{sw}}) &= 0, \end{aligned} \quad (1)$$

where $M(g_0^2, L/a, \kappa, c_{\text{sw}})$ is the bare PCAC quark mass and $\Delta M(g_0^2, L/a, \kappa, c_{\text{sw}})$ is the difference of the two bare PCAC quark masses with different definition. The actual definitions are explained in [2]. The difference from the tuning condition we employed last year is the absence of the tree-level finite PCAC quark mass which arises from the SF boundary for a finite lattice extent. The tree-level finite volume effect is tuned to the corresponding value at L^*/a by setup (iii) together with the one-loop finite volume effect.

As shown in setup (iii), we use the following one-loop perturbative correction to convert c_{sw} and κ at L/a to those at L^*/a at each g_0^2 ;

$$\begin{aligned} \kappa_c(L^*/a) &= \kappa_c(L/a) + \delta\kappa_c(L/a; L^*/a), \\ c_{\text{sw}}(L^*/a) &= c_{\text{sw}}(L/a) + \delta c_{\text{sw}}(L/a; L^*/a). \end{aligned} \quad (2)$$

$\delta\kappa_c(L/a; L^*/a)$ and $\delta c_{\text{sw}}(L/a; L^*/a)$ are defined as

$$\begin{aligned} \delta\kappa_c(L/a; L^*/a) &= [\kappa_c(L^*/a) - \kappa_c(L/a)]_{1\text{-loop}}, \\ \delta c_{\text{sw}}(L/a; L^*/a) &= [c_{\text{sw}}(L^*/a) - c_{\text{sw}}(L/a)]_{1\text{-loop}}, \end{aligned} \quad (3)$$

Figure 1. M vs ΔM at $\beta = 2.0$, $L/a = 8$.

where the right hand side of Eq. (3) is calculated up to one-loop level.

3. Results

We have carried out the numerical simulation in the region $\beta = 12.0 - 1.9$ with the setup explained in Sec. 2. It was found that below $\beta = 2.2$ the PHMC algorithm failed at vanishing or negative PCAC quark masses due to large quantum fluctuations. We extrapolated them from $M > 0$ to $M = 0$ as shown in Fig. 1. It was also found that below $\beta = 1.9$ with $L/a = 8$ it became difficult to satisfy the condition $\Delta M = 0$, which is why we employ $L^*/a = 6$ at $\beta = 1.9$ for the definition of the reference physical lattice extent.

Figures 2 and 3 are the result for c_{sw} and κ_c . Open circles are the result without L/a matching. Triangles are after tuning to L^*/a by the one-loop correction (or interpolation at $g_0^2 = 3.0$). For c_{sw} we observe large one-loop corrections in the region $1.0 < g_0^2 < 2.7$. This is due to rather strong coupling and a large discrepancy between L/a and L^*/a . We discard the data from the functional fit. At strong couplings, $g_0^2 = 6/2.2$ and $6/2.1$, the one-loop correction is rather small since $L/a \sim L^*/a$. The L/a dependence at $g_0^2 = 3.0$ ($\beta = 2.0$) is negligible compared to the statistical error (upper circle: $L/a = 8$, lower circle: $L/a = 6$). We have $6 < L^*/a < 8$ via the two-loop beta-function at $g_0^2 = 3.0$, we simply interpolate c_{sw} to L^*/a using both lattice size data. While uncorrected data undershoots the one-loop result for $L/a = \infty$ (dotted line) in the weak coupling region [1], those with one-loop correction gradually approaches it (L^*/a is essentially infi-

Figure 2. g_0^2 dependence of c_{sw} . Open circles are the result before L/a tuning. Open and filled triangles are tuned to L^*/a . Filled triangles are used for curve fitting. Solid line is the fit result. Dotted line shows the one-loop result at $L/a = \infty$.

Figure 3. Same as Fig. 2, but for κ_c .

nite in the region). For κ_c the one-loop correction is rather small. We conclude that the non-perturbative results in the weak coupling region is consistent with the one-loop one for both c_{sw} and κ_c . We fit the filled triangles to obtain the functional form in g_0^2 for c_{sw} and κ_c .

After the curve fitting including the knowledge of the one-loop perturbative coefficient we obtain

$$c_{\text{sw}}(g_0^2) = 1 + 0.113g_0^2 + 0.0209(72)g_0^4 + 0.0047(27)g_0^6, \quad (4)$$

with $\chi^2/\text{DOF} = 0.5754$, and

$$\begin{aligned} \kappa_c(g_0^2) = & 0.125 + (3.681192 \times 10^{-3}) g_0^2 \\ & + (0.141(43) \times 10^{-3}) g_0^4 \\ & + (0.124(67) \times 10^{-3}) g_0^6 \\ & - (0.049(21) \times 10^{-3}) g_0^8, \end{aligned} \quad (5)$$

with $\chi^2/\text{DOF} = 1.0014$. All data are statistically independent and χ^2/DOF results in reasonable

values. We show statistical errors only. The systematic error from the use of perturbative beta function is not estimated. We, however, consider that the systematic error is minimized since the slope in $g_0^2 = 3.0 - 3.15$ of c_{sw} should be correct because of the negligible L/a dependence at $g_0^2 = 3.0$.

4. Summary

We have extracted the non-perturbative c_{sw} as a function of g_0^2 for $N_f = 3$ with the RG-improved gauge action. The functional form is shown in Eq. (4). In deriving the non-perturbative values at a fixed physical lattice extent L^* , we used the two-loop beta-function to obtain the corresponding lattice size L^*/a at a given g_0^2 . This may contradict the word “non-perturbative”. In order to improve this point we should iteratively execute our procedure with the non-perturbative beta-function that is measured with the non-perturbative c_{sw} extracted from the previous iteration. We leave this iterative study for future studies. The first step to obtain $N_f = 2 + 1$ hadron mass spectrum has been started using the non-perturbative c_{sw} of Eq. (4) [5].
